

BPF and XDP Explained

Nic Viljoen

Give user a basic understanding of the architecture of eBPF

- What is it
- The programming model
- The kernel hooks

Give user a basic understanding of XDP

- What is it/Where is it
- How to use it (beginner level!)
- How to offload it

eBPF is a simple way to extend the functionality of the kernel at runtime

- Effectively a small kernel based machine
 - 10 64bit registers
 - 512 byte stack
 - Data structures known as maps (unlimited size)
 - 4K BPF instructions (Bytecode)
- Verifier to ensure kernel safe
 - no loops, not more than 4K insns, not more than 64 maps etc...
- Can be JITed to ensure maximum performance

Those who have publically stated they are using BPF or are planning to use BPF include

- Facebook-Load Balancing, Security
- Netflix-Network Monitoring
- Cilium Project
- Cloudflare-Security
- OVS-Virtual Switching

Due to its upstream safety and kernel support BPF provides a safe, flexible and scalable networking tool

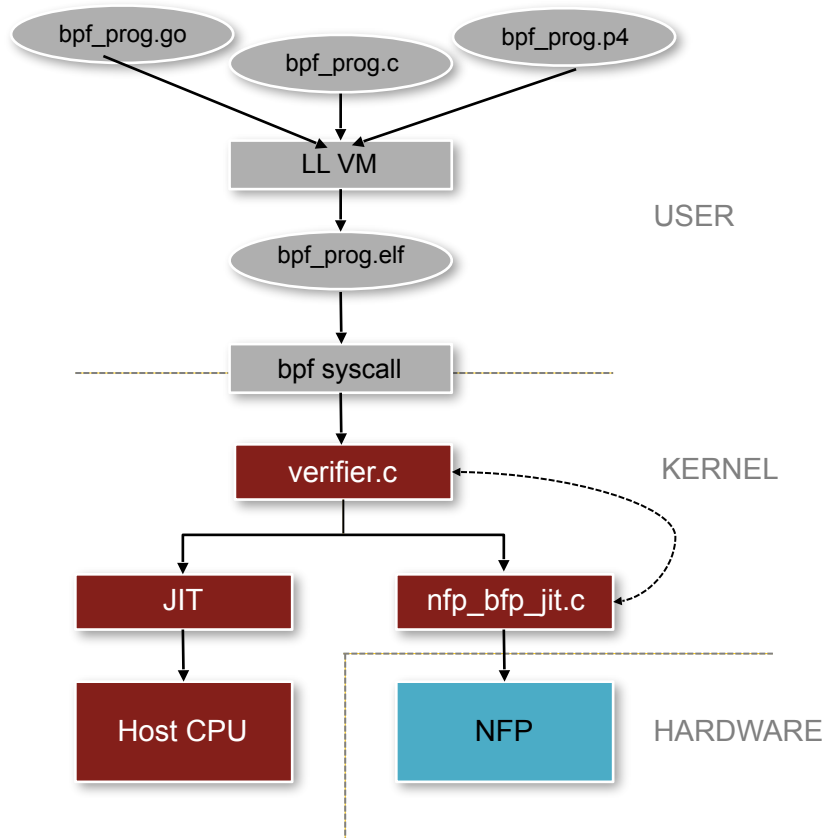

The Programming Model

LLVM is used to compile from supported languages

- C
- Go
- P4

When Programs are loaded

- Verifier is called-ensure safety
- Program is JITed-ensure perf
- Can also be offloaded
 - `nfp_bpf_jit` **upstream**

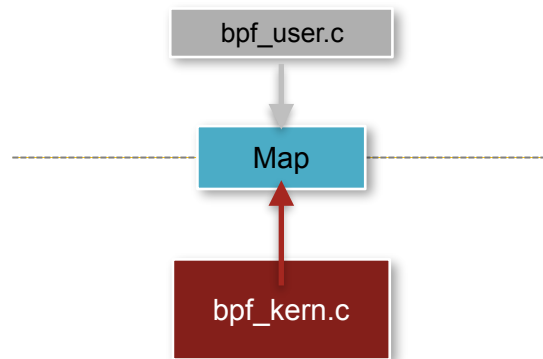

Maps are key value stores

- Can be accessed from kernel or user space
- Used for interaction between kernel and user space programs

Number of different types of maps

- Used for interaction between kernel and user space programs

```
enum bpf_map_type {  
    BPF_MAP_TYPE_UNSPEC,  
    BPF_MAP_TYPE_HASH,  
    BPF_MAP_TYPE_ARRAY,  
    BPF_MAP_TYPE_PROG_ARRAY,  
    BPF_MAP_TYPE_PERF_EVENT_ARRAY,  
    BPF_MAP_TYPE_PERCPU_HASH,  
    BPF_MAP_TYPE_PERCPU_ARRAY,  
    BPF_MAP_TYPE_STACK_TRACE,  
    BPF_MAP_TYPE_CGROUP_ARRAY,  
    BPF_MAP_TYPE_LRU_HASH,  
    BPF_MAP_TYPE_LRU_PERCPU_HASH,  
};
```

Creating Maps

THIS IS AN OVERSIMPLIFICATION

- Option 1: create map with syscall
 - `bpf(BPF_MAP_CREATE, &bpf_attr, sizeof(bpf_attr))`
- Option 2: define a struct `bpf_map_def` with an elf section `__attribute__((section("maps")))`-also uses syscall!

Option 1

```
int
bpf_create_map(enum bpf_map_type map_type,
               unsigned int key_size,
               unsigned int value_size,
               unsigned int max_entries)
{
    union bpf_attr attr = {
        .map_type    = map_type,
        .key_size    = key_size,
        .value_size  = value_size,
        .max_entries = max_entries
    };
    return bpf(BPF_MAP_CREATE, &attr, sizeof(attr));
}
```

Option 2

```
struct bpf_map_def SEC("maps") my_map = {
    .type        = BPF_MAP_TYPE_XXX,
    .key_size    = sizeof(u32),
    .value_size  = sizeof(u64),
    .max_entries = 42,
    .map_flags   = 0
};
```

eBPF Bytecode: op:8, dst_reg:4, src_reg:4, off:16, imm:32

- op code is divided into the sections
 - Operation code (4bits) e.g BPF_MOV, BPF_JNE
 - Source bit (1 bit) BPF_X (use src_reg and dst_reg) or BPF_K (use dst_reg and 32 bit imm)
 - instruction class (3 bits) e.g BPF_ALU, BPF_ALU64, BPF_JMP
- BPF_MOV | BPF_X | BPF_ALU64, 0x6, 0x1, 0x0000, 0x00000000
 - Move contents of register 1 to register 6
- BPF_JNE | BPF_K | BPF_JMP, 0x1, 0x0, 0x0011, 0x00008100
 - Jump 11 insns forward-can also jump backwards-if contents of register 1 is not equal to 0x00008100

Many hooks with different purposes

- kprobes
- socket filters-tcpdump-old school!
- seccomp
- netfilter (new)
- TC
- XDP(no skb-super fast!)

XDP will be our focus for the rest of this talk

BPF hook in the driver

- Allows for high speed processing before skb is attached to packet
- Currently 4 return codes: XDP_ABORT, XDP_DROP, XDP_PASS, XDP_TX
- XDP_REDIRECT in the pipeline
- Usecases include DDoS protection and load balancing
- Includes maximum of 256 bytes of prepend
- Metadata is just pointers to start of packet and end

```
struct xdp_md {  
    __u32 data;  
    __u32 data_end;  
};
```

Simple drop example

- Note the use of standard header infrastructure
- Associated user space program maintaining a set of counters
- I am not going to go through line by line-for more detail check out Andy and Jesper's awesome tutorial-in links
- Will come back to this example later on...

This can be found in the recent (4.8+) kernels at **linux/samples/bpf**

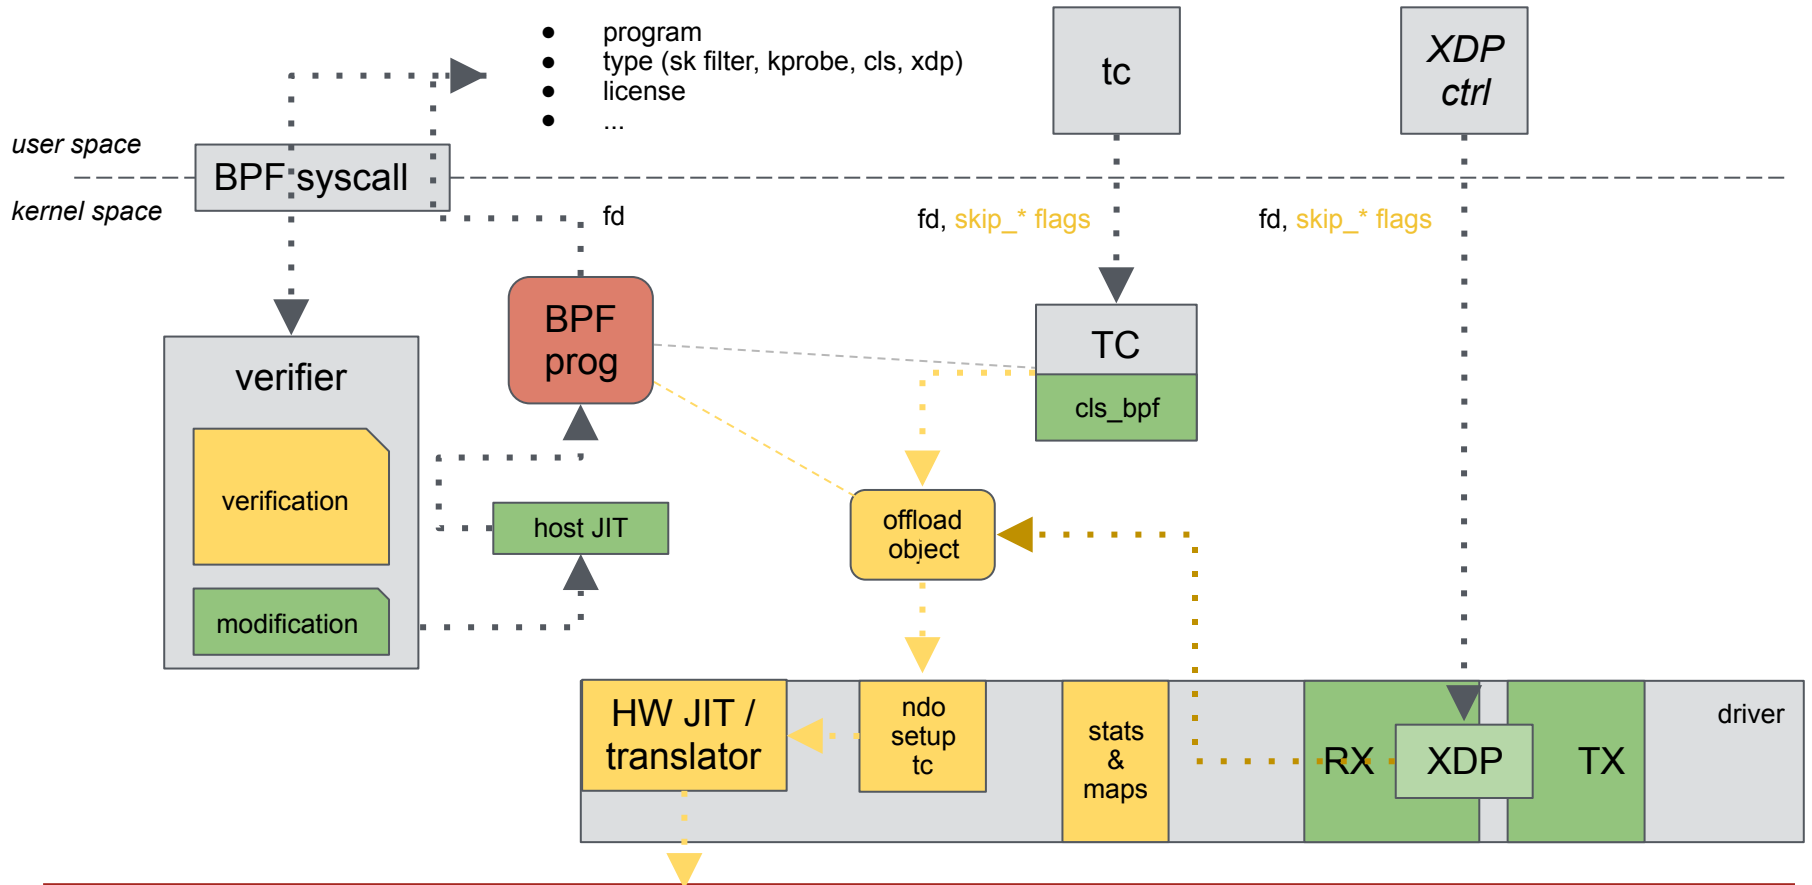

A simple checklist-not comprehensive!

- Ensure BPF JIT is enabled
- Pin queues to interfaces
- Set ringsize to an optimal level for your NIC and application
- To gain some idea of your NIC's driver based XDP performance check simple XDP_DROP and XDP_TX programs
- Many people use single core performance as a reasonable benchmark
 - To do this use the ethtool -X command
 - You will NOT get the simple program performance if you build something complex (Duh)

Netronome have upstreamed the initial version of the `nfp_bpf_jit`

- More to come!
